

Cross-Platform Content Performance Report

TikTok, YouTube Shorts & Meta (Instagram/Facebook): What the Data Says About Reach, Retention, and Growth

Prepared from account analytics exports · August 2026

Executive Summary

This report is built entirely from raw analytics exports pulled from three accounts: YouTube Studio, TikTok Creator Tools, and Meta Business Suite. It covers 259 published YouTube Shorts, seven days of TikTok viewer data, and 28 days of Meta (Instagram/Facebook) performance. Rather than starting from general best practices, the recommendations below start from what the numbers on these specific accounts already show working.

Headline numbers:

- YouTube: 395,458 total views across 259 Shorts, 769 hours of watch time, 42 new subscribers
- TikTok: 62,152 total viewers over the last 7 days, with one video driving a 58,686-viewer outlier day
- Meta: 15,587 views / 11,866 viewers over 28 days with only 90 interactions and 5 new follows on typical posts, but one outlier Reel (outside that window) pulled 1.1M views and 174 follows on its own, proving the ceiling is much higher than the daily baseline suggests

The through line across all three platforms: reach is not the constraint. Duration, hashtag selection, and publish timing on YouTube already show strong, learnable patterns. TikTok and Meta both show this account can produce breakout spikes, including a 58,686-viewer day on TikTok and a 1.1M-view Reel on Meta, when a hook lands. The gap is between typical day-to-day output and those outlier moments, and closing it is a writing and CTA problem more than a reach problem.

YouTube Shorts: The Clearest Signal in the Data

With 259 published Shorts, this is the largest dataset of the three and the one where patterns are statistically meaningful rather than anecdotal.

Shorter is measurably better

Videos were bucketed by length and compared on average views:

Figure 1: Average views by video length, all 259 Shorts.

Videos under 10 seconds average 3,909 views, more than double the 11-20 second bucket (1,335) and nearly 5x the 31-60 second bucket (800). The correlation between duration and views across the full dataset is negative ($r \approx -0.16$), confirming this isn't a small-sample fluke. The account's audience rewards a fast, single-beat joke over a longer setup-and-payoff structure.

Tuesday is the strongest publish day

Figure 2: Average views by day of week the video was published.

Tuesday uploads average 3,502 views, roughly double every other day, and 4x Monday (864, the weakest day). Saturday (1,900) and Thursday (1,658) are secondary strong days. This is a strong enough gap that shifting the primary upload slot to Tuesday, with Saturday as a secondary slot, is a low-risk, high-confidence change.

Hashtags: niche and specific outperforms broad

Figure 3: Average views for hashtags used 5+ times, ranked by performance.

The broad, high-frequency tags, including #comedy (used 206 times), #funny (165), and #standupcomedy (92), actually underperform the average. The tags that convert best are more specific: #hahaha (4,492 avg views), #satire (3,247), #laughs (2,934), and #lgbt (2,787), a topic-specific tag tied to a single high-performing video. This suggests the algorithm is rewarding tag specificity and topical relevance over sheer category volume: a smaller, sharper tag set beats a maximal one.

What this means for the writing layer

- Lead with the punchline, not a setup: the data rewards videos that resolve in under 10 seconds
- Titles should carry 3-5 specific, topic-relevant hashtags rather than 8-10 generic comedy tags
- Batch-produce and schedule for Tuesday/Saturday release rather than a daily-drip approach

TikTok: Proof the Account Can Break Out

Figure 4: Total viewers per day, last 7 days.

TikTok's most recent week shows a single dramatic spike: July 31 delivered 58,686 viewers against a baseline of roughly 200-900 viewers on every other day, a 65-100x jump. Critically, 58,501 of those viewers (99.7%) were new, not returning, meaning this was a genuine discovery-page breakout rather than an existing-audience event.

Two things matter about this spike for a writing strategy:

- It proves the account's content style is fully capable of FYP-scale distribution when a video's hook lands: this isn't a ceiling problem
- The seven-day baseline (excluding the spike) sits far lower, meaning the gap between an average post and a breakout post is almost entirely in the opening-hook writing, not production value or topic choice

The immediate opportunity: identify what made the July 31 video's hook different from the surrounding days' videos, and treat that opening line/frame structure as a template to test again rather than a one-off.

Meta (Instagram/Facebook): Reach Without Conversion

Figure 5: Daily viewers and views, 28-day window.

Meta shows a real, if modest, viewership base, averaging 424 viewers and 557 views per day over 28 days, with a strong peak of 4,491 viewers on July 13. But that traffic isn't converting:

Figure 6: Full engagement funnel, 28-day totals (log scale).

Stage	28-day total	Rate from prior stage
Views	15,587	N/A
Viewers	11,866	76.1% of views
Interactions	90	0.76% of viewers
Profile visits	29	0.24% of viewers
New follows	5	0.04% of viewers

Table 1: Meta conversion funnel, 28-day totals.

This is the clearest gap in the whole dataset. A YouTube-scale audience is watching Meta content (11,866 viewers in 28 days), but fewer than 1 in 100 do anything after watching: no like, comment, save, profile

visit, or follow. On a platform where the algorithm explicitly weights saves and shares over views, this pattern signals that the content is being watched but the caption, on-screen text, and CTA aren't giving viewers a reason to act.

Who's actually watching

Figure 7: Age and gender breakdown of Meta audience.

The Meta audience skews heavily male (91.5% vs. 8.5% female) and concentrated in the 25-54 range, with 35-44 the single largest segment (32.8% of total audience). Geographically, 75.6% of the audience is U.S.-based, with the U.K. (9.6%), Canada (8.1%), and Australia (6.1%) forming a secondary English-speaking tier.

This is a specific, well-defined audience, which makes the low conversion rate more fixable than if the audience were scattered. Copy and CTAs can be written for one clear reader (a man in his 30s-40s, U.S.-based) instead of a generic audience.

What this means for the writing layer

- Every caption needs one explicit, single CTA, such as 'save this,' 'send this to someone who,' or a specific link-in-bio action, placed at the end after the payoff, not buried at the top
- Given the save/share-weighted algorithm, reframe some jokes as list- or reference-style posts ('3 things that...') that give viewers a functional reason to save
- Bio and link-in-bio copy should be rewritten to state plainly what happens when someone clicks: profile visits (29) are already low relative to viewers, so the handoff itself needs to earn the click

Meta Case Study: A Second Breakout Reel

One additional Reel surfaced after the initial export. Its publish date falls outside the 28-day window pulled for the daily timeline, so it isn't in the Meta Daily sheet or the funnel totals above. At 9 seconds long and posted separately, it's large enough on its own to change the read on Meta's conversion story, so it's presented here as a standalone case study rather than folded into the daily averages.

Reach and retention:

- 1,100,286 views · 619,599 accounts reached · 10s average watch time on a 9s video (viewers are

watching the loop back around)

- 99.3% of viewers were non-followers: this was almost entirely cold discovery-page traffic, not existing audience

Engagement:

- 35,628 likes (5.8% like rate, above benchmark) · 504 comments · 606 reposts
- 56,699 shares, a 9.2% share rate, above benchmark, and the strongest single signal on the video
- 2,553 saves (0.4% save rate, above benchmark) · 14.8% skip rate, below benchmark, meaning fewer people scrolled past than typical

Conversion:

- 343 profile visits · 174 new follows · 2 bio-link taps

This single Reel drove more views (1.1M) than the entire 28-day daily export combined (15,587), and converted 174 follows against it, more than 30x the 5 follows the whole 28-day window produced. It's proof of the same pattern already seen on TikTok: this account is fully capable of algorithm-scale breakout distribution and real conversion when a video's hook and pacing land. The share rate (9.2%, above benchmark) is the standout metric. On a platform where shares are one of the strongest ranking signals, this is the kind of result worth reverse-engineering the same way the TikTok July 31 spike is.

The audience this Reel reached skews younger and more international than the account's 28-day Meta baseline: 47.4% aged 25-34 (vs. a 35-44-skewed baseline), and meaningful Spanish- and Portuguese-speaking viewership (5,324 and 1,097 views respectively) that doesn't show up in the English-dominant, U.S.-heavy 28-day audience snapshot. That's worth treating as a signal, not noise: this content style may be opening a genuinely different, younger, more international audience segment that the account's regular posting isn't currently reaching.

Figure 8: Reel insights screenshots: Overview, Engagement, and Audience tabs.

Updated takeaway for Meta: the earlier conversion-gap finding still holds for typical day-to-day posts, but this Reel shows the ceiling is much higher than the 28-day baseline suggests. The highest-leverage Meta action is now twofold: tighten the CTA/caption layer on regular posts, and specifically study what this Reel's opening 9 seconds did differently so it can be repeated.

Cross-Platform Takeaways

Platform	Strength shown in data	Primary gap	Highest-leverage fix
YouTube Shorts	Clear, learnable patterns (length, day, tags)	Inconsistent application of the winning pattern	Standardize on <10s length, Tue/Sat publishing, niche tags
TikTok	Proven capacity for 60-100x breakout reach	Spike isn't repeatable/understood yet	Reverse-engineer and re-test the July 31 hook
Meta	Proven 1M+ view ceiling (outlier Reel) plus stable baseline (11.8K viewers/28 days)	Typical posts convert near zero (0.04% follow rate) vs. the outlier's strong 9.2% share rate	Rewrite every caption around one explicit CTA; study the outlier Reel's hook

Table 2: Summary of findings and next actions by platform.

Across all three platforms, the pattern is consistent: this account does not have a discovery problem. YouTube already reaches hundreds of thousands of views, TikTok has proven six-figure-scale breakout potential, and Meta sustains a real, demographically well-defined audience. The highest-leverage work from here is not chasing more reach. It's tightening the writing layer (hook structure, caption CTAs, hashtag specificity) so the reach already being earned converts into subscribers, follows, and traffic at a higher rate.

Full underlying data, including every video, every daily data point, and the audience breakdown, is provided in the companion spreadsheet, [social_media_data.xlsx](#).
